

Making extensions

Making extensions for *Cerbo* is simple and don't need a lot of configuration files because everything is discovered automaticaly.

Creating an extension and activating it

First, you need to create a folder with your extension's name in `/extensions`.

Then, you only have to add the extension to the list of the used extensions in `/settings/application.ini`.

```
[EXTENSIONS]
Use[]=cerbo
Use[]=administracio
Use[]=your_application_folder_name
```

Basic structure of extensions

Once you have a new extension folder, you can add the following folders :

- **classes** : For the classes of your application.
- **design** : For the design files.
- **modules** : For the available modules.
- **settings** : For the configuration files.
- **translations** : For the translations dedicated to your classes and modules.

Classes

Classes are free but you should made class names like :

```
<extension name><class name>
```

For exemple, if your extension's name is *Foo* and your logical class name is *Bar*, the real classname should be *FooBar* to avoid possible classnames scope.

Design
