

## Easy ajax

With *Cerbo*, it is very easy to fetch data for ajax requests.

Every content that can be displayed as a web page could (if the developers of the extensions followed the specifications) be fetched as a JSON or XML content.

### How to access those formats ?

For every pages you can add `.json` or `.xml` to the URI :

```
# The 'standard' format  
mywebsite.tld/mypage
```

```
# Get data as a JSON structure  
mywebsite.tld/mypage.json
```

```
# Get data as an XML file  
mywebsite.tld/mypage.xml
```

### I'm a dev, how should I implement that ?

As you should know, each module extends from `\cerbo\kernel\Module` who extends from `\cerbo\kernel\Content` and who force you to implements two dedicated methods :

- `toJSON()` who returns the content as a valid JSON (and, of course, as a `string`).
- `toXML()` who returns the content as a valid XML (and, of course, as a `string`).

**NB** : Pages have already those methods. Please read the documentation about *Making templates for Page*.
